

LEAD CAPTURE AUTOMATION

Project Documentation

Mina JK · Malmö, Sweden

PROJECT STATUS

Functional portfolio demonstration built and tested with demonstration submissions. It was not deployed in a live client environment.

Purpose: document the workflow logic, testing, limitations and implementation thinking in a clear, interview-ready format.

1. Project brief

Problem

When a website enquiry arrives as an email, someone would otherwise need to open it, copy the lead details, check that the required fields are present, add the lead to a shared sheet, notify the team and send a reply. That creates several manual steps and increases the chance of missed or inconsistent follow-up.

Solution

A single Make.com scenario receives the Webflow form submission through a Make.com Mailhook, extracts the lead fields with Text Parser, validates the required data, logs valid leads in Google Sheets, notifies the team in Slack and sends an automatic confirmation through Outlook.

MY ROLE

I planned, built, tested and documented the automation independently.

Tool	Responsibility
Webflow	Source of the website enquiry
Make.com Mailhook	Trigger / entry point for the submitted message
Text Parser	Extracts name, email and message from the email body
Filter	Checks required lead data before follow-up actions
Google Sheets	Stores validated leads in a shared log
Slack	Notifies the team when a valid lead arrives
Outlook	Sends the automatic confirmation reply

2. Workflow design

Planning sketch — the intended lead-capture flow.

Implemented Make.com scenario. The filter sits between Text Parser and Google Sheets.

- 1 • **Capture:** Webflow sends the submitted form message to the Make.com Mailhook. The Mailhook is the workflow trigger.
- 2 • **Parse:** Text Parser reads the email body and extracts the lead fields as separate values.
- 3 • **Validate:** The filter requires all three conditions to pass: name exists, email exists, and email contains '@'.
- 4 • **Log:** A valid lead is added as a new row in Google Sheets.
- 5 • **Notify:** Slack sends an internal message so the team sees the new lead immediately.
- 6 • **Reply:** Outlook sends an automatic confirmation to the person who submitted the form.

INVALID SUBMISSION BEHAVIOUR

If any validation condition fails, the workflow stops before Google Sheets, Slack and the confirmation reply. This prevents incomplete data from triggering follow-up actions.

3. Scope and implementation assumptions

In scope

- Webflow form submission delivered to a Make.com Mailhook
- Parsing name, email and message from the submitted email body
- Basic validation: name exists, email exists, email contains '@'
- Google Sheets lead log, Slack team notification and Outlook confirmation
- Testing with demonstration submissions and project documentation

Out of scope in the current version

- CRM integration, lead scoring and sales-pipeline automation
- Duplicate detection
- Email deliverability or ownership verification
- Automatic retries, failure monitoring and production alerting
- High-volume production storage and live-client deployment

4. Planned acceptance criteria — not measured client results

IMPORTANT

These are acceptance targets for a production-style implementation. They are not measured business results from a live client environment.

Test / target	Condition	Expected behaviour
Valid lead	Name + email present and email contains @	Continues to Sheets, Slack and Outlook
Missing name	Name condition fails	Stops before follow-up actions
Missing email	Email condition fails	Stops before follow-up actions
Malformed email	Email does not contain '@'	Stops before follow-up actions
Shared log	Valid demonstration submission	A new row is created in Google Sheets
Internal notice	Valid demonstration submission	Slack message is generated
Confirmation	Valid demonstration submission	Outlook confirmation is generated

5. Example implementation plan

PLANNING NOTE

The timeline below is an example production-style plan, not a claim about a real client engagement.

Phase	Example timing	Focus
1. Requirements	Day 1	Confirm fields, sheet columns, notifications and acceptance criteria
2. Capture setup	Day 2–3	Connect Webflow submission to Make.com Mailhook and verify input
3. Parsing & validation	Day 4–5	Extract fields and configure validation conditions
4. Logging	Day 6	Create Google Sheets structure and mapping
5. Notification & reply	Day 7	Configure Slack and Outlook actions
6. Testing & fixes	Day 8–9	Run valid and invalid test cases and correct issues
7. Handover	Day 10	Final review and documentation

6. Testing performed

The workflow was tested with demonstration submissions. The main modules and all three validation conditions were checked; it was not deployed in a live client environment.

Test case	Expected result
Complete name + valid-looking email + message	Flow continues to Sheets, Slack and Outlook
Name missing	Filter stops the flow
Email missing	Filter stops the flow
Email without '@'	Filter stops the flow
Consistent Webflow email format	Text Parser extracts the intended fields

7. Current limitations and risks

Area	Current limitation / risk	Production response
Parser dependency	A change in the Webflow email-body format could break the parsing pattern.	Document the expected format and retest after changes.
Basic email validation	The current filter only checks presence and '@'.	Use stronger validation in a production version.
No duplicate detection	The same person can submit more than once and create more than one row.	Add duplicate checks, for example by email plus submission time or a unique ID.
Google Sheets scaling	Sheets is suitable for the demonstration but not ideal for high-volume production use.	Move to a CRM or structured database if volume grows.
Action failures	Slack or Outlook could fail after validation.	Add error handling, retries, logging and monitoring.
Personal data	Lead information can include personal data.	Limit access, minimize stored data and add production privacy/consent handling.

8. Planned improvements

- Replace or complement Google Sheets with a CRM or structured database
- Add duplicate detection
- Strengthen email validation beyond the current @ check
- Add error logging, retry routes and monitoring for failed actions
- Add lead-source tracking
- Add consent and privacy handling appropriate to a production form

9. Interview quick recap

30-SECOND SUMMARY

I built a Make.com lead-capture workflow that receives a Webflow form submission through a Mailhook, parses the lead fields, validates the required data, logs valid leads in Google Sheets, notifies the team in Slack and sends an Outlook confirmation. The key design decision is that validation happens before any follow-up action. The current version is a tested portfolio demonstration, not a live client deployment.

Question	Short answer
What problem does it solve?	Manual copying, inconsistent follow-up and leads staying in individual inboxes.
What is the key logic?	Validate required data before logging, notification and reply.
What happens to invalid data?	The flow stops before follow-up actions.
Biggest current limitation?	Basic validation, no duplicate detection and no production retry/monitoring.
What would you improve next?	CRM/database storage, stronger validation, duplicate checks and error handling.
